22nd International Grassland Congress, Organising Committee

President
Professor David Kemp, Charles Sturt University, Orange, New South Wales, Australia

Coordinator, Scientific Program and Chief Editor
Dr David Michalk, NSW Department of Primary Industries, Orange, New South Wales, Australia

Coordinator, Sponsorship
Dr Bob Clements, former Chair of the IGC Continuing Committee, Australian Capital Territory, Australia

Coordinator, Satellite Meetings and Tours
Emeritus Professor Ted Wolfe, Charles Sturt University, Wagga Wagga, New South Wales, Australia

Executive Officer
Dr Warwick Badgery, NSW Department of Primary Industries, Orange, New South Wales, Australia

Treasurer
Dr Karl Behrendt, Charles Sturt University, Orange, New South Wales, Australia

Committee Members
Dr Hugh Dove, CSIRO Division of Plant Industries, Canberra, Australian Capital Territory, Australia
Dr Anton Southwell, Charles Sturt University, Wagga Wagga, New South Wales, Australia
Dr Michael Friend, Charles Sturt University, Wagga Wagga, New South Wales, Australia
Dr Rex Stanton, Charles Sturt University, Wagga Wagga, New South Wales, Australia

International Fundraising
Dr James O'Rourke, Chardon, NE, USA

Many colleagues were called upon to aid in various ways, we thank them all.

Integrating mechanical and cultural control treatments to manage the invasive shrub *Chromolaena odorata* in grassland areas

M Rusdy and EK Budiman

Faculty of Animal Husbandry, Hasanuddin University, Jl. Pertinjauan Kemotokan Km. 10 Makassar, Indonesia
Contact email: mrusdy37@gmail.com

Keywords: *Chromolaena odorata*, integrated mechanical and cultural controls, weed suppression, botanical composition.

Introduction

*Chromolaena odorata* (L.) King and H. Robison, is a major invasive weed of pastures and plantation crops in many countries and has become one of the worst invasive plants in grassland areas in Indonesia. *Chromolaena* can grow rapidly and form infestations that can suppress pasture by competing for nutrients and water, and by shade and flowering. Its allelopathic effect lowers productivity of desirable forage species with a consequent loss of livestock production. *Chromolaena* leaves, especially when young, are toxic to animals due to high levels of nitrate (5-6 times above toxic levels) (Sajise 1974).

Control of *Chromolaena* is difficult due to its ability to thrive in a wide variety of soils, rapid attainment of reproductive maturity, large production of easily dispersed seed and a strong ability to regrow after burning (Witkowski and Wilson 2001). The present experiment was conducted to evaluate the efficacy of integrating mechanical and cultural control methods to suppress regrowth of *Chromolaena* and other weeds and to determine the influence of *Chromolaena* management on botanical composition.

Materials and Methods

This study was conducted during the dry season in a grassland in South Sulawesi, from July to November 2012. The treatments were: T1 slashing of *Chromolaena* every month, T2 digging up of *Chromolaena* and left on the soil surface (trailing), T3 digging up of *Chromolaena* followed by burning, T4 digging up of *Chromolaena* followed by burning and sowing with *Centrosema peregrinum*, and T5 digging up of *Chromolaena* followed by burning and planting with *Brachiaria decumbens*. Efficacy of treatments was measured by dry weight of weeds produced. The experiment was conducted in plots measuring 5.0 x 5.0 m, with all treatments replicated three times.

Results and Discussion

The dry yield of dominant plants during the study are shown in Table 1. Dry yield of *Chromolaena* after digging up integrated with other treatments was negligible, but dry yield of other weeds increased. This indicates that digging up is more effective in controlling regrowth of *Chromolaena* but not other weeds. The negligible regrowth of *Chromolaena* in this study may be attributed to the low germination of this weed as affected by a limited available water in the soil as most of this study occur in heavy drought in which total rainfall during the study (August to November) was only 229 mm. The low germination of *Chromolaena* during the dry season was also noted by McFadyen (2003), although some seed appears to remain dormant for several years.

Burning of *Chromolaena* followed by planting with *Brachiaria decumbens* was the most effective in suppressing weeds. This is in line with Rencan and Xuqun (2012) in southern China who reported that in the first two years of establishment, *Brachiaria decumbens* in pasture effectively prevented germination and seedling growth.

of Chromolaena. The high efficacy of Brachiaria may be attributed to the vigorous nature of Brachiaria growth and its ability to extract growth resources from the soil.

Botanical composition was shifted with treatments. In monthly slashed plots the dominant plants were Chromolaena and Stachyuraphis jamaicensis and in mowed plots, the dominant species were C. pseudogigantea and Stachyuraphis. In burnt plots, the dominant species was Mansoa pudica, indicating that burning stimulated germination and seedling growth of this plant. This is in line with reports of De-Menezes and Rosel (2011) that burning of Mansoa seeds can kill surface seeds but not buried seeds and may stimulate seeds germination due to removal of seed coat. In contrast, in this study the botanical composition of Stachyuraphis in burnt plots was lower compared to that of unburnt plots. This may be attributed to destruction of Stachyuraphis seeds at the soil surface by burning, which is the optimum depth for germination and emergence (Díaz-Pilho 1993).

Conclusion

From this study, it can be concluded that digging out of Chromolaena, followed by burning and planting with Brachiaria decumbens is the most promising method to control this weed in grassland area. It needs further study how this grass can control this weed in the rainy season and how to manage this grass in order to get high animal production while continuing to control this weed.
